I, DAVID DANIEL CLARKE , ASSISTANT DIRECTOR PATENT SERVICES,
hereby certify that the annexed are true copies of the Provisional specification and
drawing(s) as filed on 16 March 1995 in connection with Application No. PN 1789
for a patent by THE UNIVERSITY OF MELBOURNE filed on 16 March 1995.

I further certify that the annexed documents are not, as yet, open to public inspection.

Patents Act 1990

PROVISIONAL SPECIFICATION

APPLICANT: THE UNIVERSITY OF MELBOURNE

TITLE: ANTIGEN COMPOSITION

This invention is described in the following statement:

ANTIGEN COMPOSITION

The present invention relates to protective and diagnostic antigens, the preparation thereof, and their use in the formation of vaccine compositions, particularly vaccine compositions against Mycoplasma hyopneumoniae infections.

5 Mycoplasma hyopneumoniae is a ubiquitous swine respiratory pathogen causing mycoplasmal pneumoniae in swine (swine enzootic pneumonia). Swine enzootic pneumonia is probably the most widespread and economically significant disease in swine producing countries of the world. The economic effects of swine enzootic pneumonia (SEP) are complex, and the cost of the disease is severe. In Australia, the
10 disease was estimated in 1988 to cost approximately \$20,000,000 per annum. Increased mortality, decreased growth weight, depressed feed conversion, susceptibility to secondary bacterial infections, increased management costs, and increased use of antibiotics, are the main reasons for the economic impact of SEP.

 Whilst several experimental vaccines have been produced, these have resulted
15 in less than optimal results, and utilising various classes of antibiotics such as tetracycline, lincamycin and tiamulin is still the most widespread control treatment. Such antibiotics are, however, of limited therapeutic value, because they do not prevent the establishment of an infection, and lung lesions may develop after treatment ends.

 European Patent Application 359,919 to ML Technology Ventures L.P. describes
20 a series of antigens, 36 kD, 41 kD, 74.5 kD and 96 kD in size, and proposes the use of such antigens in vaccines. Results presented suggest that some protection in pigs against challenge was achieved.

 However, there remains a need in the art for an effective vaccine against M. hyopneumoniae which would confer protection against colonisation and clinical disease
25 following M. hyopneumoniae challenge and also significantly reduce the morbidity and mortality from secondary infections.

 Accordingly, it is an object of the present invention to overcome, or at least alleviate, one or more of the difficulties and deficiencies in the prior art.

 Accordingly, in a first aspect of the present invention there is provided a
30 protective antigen against a Mycoplasma, preferably Mycoplasma hyopneumoniae prepared by a method including

 providing

a sample of a Mycoplasma;

an antibody probe including at least one antibody against a Mycoplasma produced by a method including;

providing a biological sample taken a short time after an immune animal has been challenged with a Mycoplasma or Mycoplasma extract taken from the infection site or an area of a lesion or an area close to the infection site or lesion;

isolating cells from the biological sample;

culturing cells in vitro in a suitable culture medium; and

harvesting antibodies produced from said cells;

probing the Mycoplasma sample with the antibody probe to detect at least one antigen; and

isolating the antigen detected.

The protective antigens may also function as diagnostic antigens as discussed below.

Accordingly, in a preferred aspect of the present invention there is provided a putative protective antigen against Mycoplasma hyopneumoniae, or related infections, selected from antigens having approximate molecular weights of 110-114, 90-94, 72-75, 60-64, 52-54 and 46-48 kilodaltons (kD), as hereinafter described, mutants, derivatives and fragments thereof. The protective antigen may be a surface protein. The protective antigen may be a surface lipoprotein or membrane protein.

Preferably the protective antigens are selected from antigens having approximate molecular weights of 110-114, 90-94, 74, 62, 52 and 48 kD.

Preferably, the 72-75 kD antigen includes the following N-terminal amino acid sequence:

AGNLQKNSLLEEVWYLAL

and, optionally, one or more of the following internal amino acid sequences:

AKNFDFAFSIQGYKKIAHEL

NLKPEQILQLLG

LLKAEXNKXIEEINTXLDNLIK

Preferably, the 60-64 kD antigen includes one of the following N-terminal amino acid sequences:

MKLAKLLKGFX(N/L)(M/V)IK

ADP(F/I)(R/E)Y(V/A)PQG(Q/A)X(M/N)VG

Preferably, the 52-54 kD antigen includes the following N-terminal amino acid sequence:

5 AGNWAKETTKEEKS

and, optionally, one or more of the following internal amino acid sequences:

AWWTADGTVN

AIVTADGTVNDNKPNQWVRKY.

10 Preferably, the 46-48 kD antigen includes the following N-terminal amino acid sequence:

AGNGQTESGSTNDEKPQAEIPAHKV

and, optionally, one or more of the following internal amino acid sequences:

TIYKPDKVLGKVAVEVLRVLIKKNKASR

AEQAITKLKXXXXFDTQ

15 KNXGWKIIDLXPEG

The 46-48 kD antigen may be encoded by a nucleic acid fragment including one or more of the following nucleic acid sequences:

ACGAACGATG	AGAAACCGCA	GGCCGAGACG	CTAAACATA	AAGTAAGTAA
TGATTCTATT	CGAATAGCAC	TAACCGATCC	GGATAATCCT	CGATGAATTA
GTGCCCAAAA	AGATATTATT	TCTTATGTTG	ATGAAACAGA	GGCAGCAACT

TCCAGCAGGT	GGTAATAAAA	TCAA; and		

20

CAAAGGATTT	CTTGCCCCAA	ATGATGGAAT	GGCCGAGCAA	GCCATCACCA
AGTTCAA.				

Accordingly, in a further aspect the present invention provides an isolated nucleic acid fragment encoding a putative protective antigen against Mycoplasma hyopneumoniae or related infections, said nucleic acid fragment including one or more
25 of the following sequences, mutants, derivatives and fragments thereof:

ACGAACGATG	AGAAACCGCA	GGCCGAGACG	CTAAAACATA	AAGTAAGTAA
TGATTCTATT	CGAATAGCAC	TAACCGATCC	GGATAATCCT	CGATGAATTA
GTGCCCAAAA	AGATATTATT	TCTTATGTTG	ATGAAACAGA	GGCAGCAACT
TCAACAATTA	CAAAAAACCA	GGATGCACAA	AATAACTGAC	TCCTCAGCA
AGCTAATTTA	AGCCCAGCGC	CAAAAG;		
ACAATCGCGG	GTTCCCAAGA	TGATAATAAT	TCCCAATATT	TTTATAATGG
TGCAATGAAA	GTAATAAG	AATTAATGAA	AAATTCGGGA	AATAAAATAA
TTGATTTATC	TCCTGAAGGC	GAAAATGCTG	TTTATGTCCC	AGGATGAAAT
TATGGAAGCTG	CCGGTCAAAG	AATCCAATCT	TTTCTAACAA	TTAACAAAGA
TCCAGCAGGT	GGTAATAAAA	TCAA; and		
CAAAGGATTT	CTTGCCCCAA	ATGATGGAAT	GGCCGAGCAA	GCCATCACCA
AGTTCAA.				

As cross protection between various Mycoplasma such as M. hyorhinis and M. synoviae has been documented, similar antigens may also be detected in other Mycoplasma species (Figure 1).

In a still further aspect the present invention provides a method for preventing Mycoplasma infection in animals. Preferably the Mycoplasma disease is a Mycoplasma hyopneumoniae disease such as swine enzootic pneumonia (SEP). This method includes administering to an animal an effective amount of at least one protective antigen against Mycoplasma as described above.

The present invention further provides a vaccine composition including a prophylactically effective amount of at least one protective antigen against a Mycoplasma as herein described. Preferably the veterinary composition includes two or more protective antigens as herein described.

Accordingly in a preferred aspect the present invention provides a vaccine composition including two or more protective antigens selected from antigens having approximate molecular weights of 110-114, 90-94, 72-75, 60-64, 52-54 and 46-48 kilodaltons.

The vaccine composition may include any combination of two or more protective antigens selected from antigens having approximate molecular weights of 110-114, 90-94, 72-75, 60-64, 52-54 and 46-48 kD. The two or more antigens may be selected from antigens falling within one of the specified approximate molecular weights and/or antigens from different specified approximate molecular weights. The composition may contain 3, 4, 5 or 6 antigens selected from protective antigens having molecular weights of approximately 110-114, 90-94, 72-75, 60-64, 52-54 and 46-48 kD.

The vaccine compositions according to the present invention may be administered orally or may be administered parenterally (for example by intramuscular, subcutaneous, intradermal or intravenous injection). The amount required will vary with the antigenicity of the active ingredient and need only be an amount sufficient to induce
5 an immune response typical of existing vaccines.

Reactive experimentation will easily establish the required amount. Typical initial doses of vaccine or veterinary compositions may be approximately 0.001-1 mg active ingredient/kg body weight. The dose rate may increase or multiple doses may be used as needed to provide the desired level of protection.

10 The vaccine composition according to the present invention may further include a veterinary acceptable carrier, diluent or excipient therefor. Preferably the active ingredient may be suspended or dissolved in a carrier. The carrier may be any solid or solvent that is nontoxic to the animal and compatible with the active ingredient. Suitable carriers include liquid carriers, such as normal saline and other nontoxic salts
15 at or near physiological concentrations, and solid carriers, such as talc or sucrose.

Preferably the vaccine contains an adjuvant, such as Freund's adjuvant, complete or incomplete, or immunomodulators such as cytokines may be added to enhance the antigenicity of the antigen if desired.

More preferably the adjuvant is of the mineral-oil type as these have been found
20 to be consistently superior at inducing antibody titres and Delayed Type Hypersensitivity responses. A particularly preferred adjuvant is that marketed under the trade designation Montanide ISA-50 and available from Seppic, Paris, France.

When used for administering via the bronchial tubes, the vaccine is suitably present in the form of an aerosol.

25 In a still further aspect of the present invention there is provided a diagnostic kit including a diagnostic antigen against a Mycoplasma, preferably Mycoplasma hypneumoniae, identified and purified as described above.

The protective antigens according to the present invention may be isolated and identified utilising the general methods described in Australian patent application
30 49035/90, the entire disclosure of which is incorporated herein by reference.

Accordingly, in a further aspect, the present invention provides a method for producing at least one antibody against a Mycoplasma. This method includes

providing a biological sample taken a short time after an immune animal has been challenged with a Mycoplasma or Mycoplasma extract taken from the infection site or an area of a lesion or an area close to the infection site or lesion;

isolating cells from the biological sample;

- 5 culturing cells in vitro in a suitable culture medium; and
harvesting antibodies produced from said cells.

The Mycoplasma may be Mycoplasma hyopneumoniae.

The animal may be a mammal including humans. The mammal may be a domestic animal such as a pig, sheep or cattle.

- 10 The biological animal sample may be of any suitable type. The biological sample may be taken from animal tissue, organs, lymph or lymph nodes. The biological sample may be taken from the infection site, the lungs of the animal, or an area of a lesion which may be formed or an area close to the infected site or a lesion such as in the lymph nodes draining from the lungs.

- 15 However, serum/plasma samples are not used as the biological samples according to this aspect of the present invention. It has been found that the majority of antibodies found in a serum/plasma sample are irrelevant to protection or specific diagnosis or a Mycoplasma or are unrelated to the Mycoplasma. In addition, other serum/ plasma components may interfere with the specific reactions between pathogen
20 components and antibodies to them.

In contrast, the probes described in the present invention are highly enriched in Mycoplasma-specific antibodies of particular importance to protective immunity.

- It is preferred that the biological samples are taken from the animals at a predetermined time in the development of the disease. In general, for a Mycoplasma
25 infection, it has been found that the biological samples should be taken approximately 2 to 7 days after challenge with or after administration of products obtained from a pathogen or with the pathogen itself.

The cells isolated from the biological sample may include B cells.

- Thus, preferably the cells are taken a short time after in vivo stimulation,
30 preferably within approximately 2 to 5 days thereafter, resulting in the in vivo induction of antibody forming cells which will secrete specific antibodies into the culture medium after in vitro incubation.

In vitro secretion of antibodies in the culture medium by recently activated B cells may be enhanced by the addition of helper factors to the cultures. The helper factors may be cytokines used alone or in combination, including Interleukin 1, 2, 3, 4, 5, 6, 7 and 8, colony stimulating factors, interferons and any other factors that may be shown
5 to have an enhancing effect on specific B cell secretion.

The method of producing an antibody may include a further step of activating the cells isolated to proliferate and secrete and/or release antibodies.

The cell activation step may include adding a cell activating agent to the culture medium. The cell activating agent may be selected from mitogens and helper factors
10 produced by leukocytes, or their synthetic equivalents or combinations thereof.

The mitogens may be selected from products derived from pokeweed (Phytolacca americana) also known as pokeweed mitogen (PWM), polyvinylpyrrolidone (PVP), polyadenylic-polyuridylic acid (poly(A-U)), purified protein derivate (PPD), polyinosinic-polycytidilic acid (poly(I-C)), lipopolysaccharide (LPS), staphylococcal
15 organisms or products thereof, Bacto-streptolysin O reagent (SLO), Staphylococcal phage lysate (SPL), Epstein-Barr virus (EBV), Nocardia water-soluble mitogen (NWEM), phytohemagglutinin (PHA), Concanavalin A (Con A), and dextran-sulphate and mixtures thereof. The cell proliferation agent may be any agent that indirectly or directly results in B cell proliferation and/or antibody secretion such as solid-phase anti-
20 immunoglobulin. The helper factors may be cytokines including interleukin 1, 2, 3, 4, 5, 6, 7 and 8, colony stimulating factors, interferons and any other helper factors that may be shown when added alone, or in combination with other factors and agents, to have an enhancing effect on specific B cell proliferation and/or antibody secretion. This in no way is meant to be an exhaustive list of mitogens and cell actuating agents including
25 helper factors.

The in vitro culturing of the cells may be conducted with or without prior steps to separate sub-populations of cells. The harvesting of antibodies may be conducted by harvesting of the supernatant from the culture medium. This supernatant contains antibodies secreted by these cells during the in vitro culture or artificially released from
30 the B cells, for example by lysis of the B cells. It has been found that the antibody-containing supernatants may be used directly to detect antigens of the Mycoplasma.

In a preferred aspect of the present invention, there is provided a method for

identifying an antigen associated with a Mycoplasma, preferably Mycoplasma hyopneumoniae. This method includes

providing

a sample of a Mycoplasma; and

5 an antibody probe including at least one antibody against a Mycoplasma;
probing the Mycoplasma sample with the antibody probe to detect at least one antigen; and

isolating the antigen detected.

10 The sample of Mycoplasma may be mixed with a standard buffer solution and placed on a standard support such as an SDS-polyacrylamide gel to separate the proteins contained thereon (Figure 2).

Alternatively, the proteins may be selected utilising the non-ionic detergent Triton X-114 (TX-114). Insoluble material may be removed by centrifugation. Proteins soluble in the TX-114 phase may then be precipitated out (Figure 2).

15 The separate proteins may then be transferred to nitrocellulose, nylon or other sheets.

The probing with a suitable antibody may further include subjecting the product produced thereby to a detection assay. The detection assay may include Western blot techniques. The detection assay may be an immunoprecipitation assay, a
20 radioimmunoassay, an enzyme-linked immunoassay or immunofluorescent assay (Figures 3, 4 and 5).

The antibody produced as described above may be utilized simply in the form of the supernatant harvested from the culture medium. Alternatively, the antibodies may be separated and purified.

25 In a further preferred aspect of the present invention the antibody contained in the culture medium may be used for the affinity purification, preferably immuno-affinity purification of antigen.

Accordingly, in a preferred aspect there is provided a method for purifying antigen. This method includes

30 providing

a crude antigen mixture; and

an antibody against a Mycoplasma immobilized on a suitable support;

subjecting the crude antigen mixture to affinity chromatography utilizing the immobilized antibody; and

isolating the purified antigen so formed.

The antibody is produced by the method described above.

5 Antibody can be obtained from the culture supernatant probe by conventional methods. For example, methods usually used to purify immunoglobulins from serum or plasma, e.g. precipitation with ammonium sulphate, fractionation with caprylic acid, ion exchange chromatography, or by binding and elution from immobilized protein G or protein A, may be utilized. Antibody so obtained can then be coupled to suitable
10 supports, e.g., CNBr-activated Sepharose 4B (Pharmacia), Affi-gel (Bio-RAD), or other affinity chromatography supports able to bind proteins.

Immobilized antibody can then be applied to the fractionation and purification of specific antigen from a complex Mycoplasma extract by affinity chromatography. After binding of antigen to immobilized antibody, unbound macromolecular species can be
15 washed away from the solid support with, e.g. buffers containing 1.5 M NaCl. Subsequently the antigen can be eluted from the affinity column with, e.g. low or high pH buffer or buffers containing chaotropic ions, e.g. 0.5-3.0 M sodium thiocyanate.

The application of the antibody probe to affinity chromatography enables sufficient quantities of specific antigens to be rapidly isolated from a complex crude
20 extraction mixture for biochemical characterization, amino-acid sequencing and vaccination of animal for limited protection studies. Application of affinity chromatography for obtaining antigen(s) avoids the difficulties often encountered when applying conventional biochemical techniques to the purification of an antigen about which little or no data is known. It also obviates the need to raise polyclonal or
25 monoclonal antibodies for the purpose of "analytical" affinity chromatography. Large scale preparation may, however, require the preparation of polyclonal or monoclonal antibodies.

Having identified the antigen(s) molecular biology, chemical techniques, e.g. cloning techniques, may be used to produce unlimited amounts of this antigen or,
30 alternatively, synthetic peptides corresponding to different fragments of the identified antigens may be used as a means to produce a vaccine.

Accordingly in a preferred aspect of the present invention there is provided a

method for preparing a synthetic antigenic polypeptide against Mycoplasma, preferably Mycoplasma hypneumoniae, which method includes

providing

a cDNA library or genomic library derived from a sample of Mycoplasma;

5 and

an antibody probe as described above;

generating synthetic polypeptides from the cDNA library or genomic library;

probing the synthetic polypeptides with the antibody probe; and

isolating the synthetic antigenic polypeptide detected thereby.

10 Either cDNA or genomic libraries may be used. The cDNA or genomic libraries may be assembled into suitable expression vectors that will enable transcription and the subsequent expression of the clone cDNA, either in prokaryotic hosts (e.g. bacteria) or eukaryotic hosts (e.g. mammalian cells). The probes may preferably be selected from

- 15 (i) synthetic oligonucleotide probes based on the amino acid sequence of the antigen identified and purified as described above;
- (ii) antibodies obtained from the culture medium produced as described above;
- (iii) monoclonal or polyclonal antibodies produced against the antigens identified and purified as described above;
- 20 (iv) recombinant or synthetic monoclonal antibodies or polypeptides with specificity for the antigen, e.g. as described by Ward et al., Nature, 241, pages 544-546 (1989).

The synthetic antigenic polypeptide produced in accordance with the invention may be a fusion protein containing the synthetic antigenic peptide and another protein.

25 The present invention will now be more fully described with reference to the accompanying Examples and drawings. It should be understood, however, that the description following is illustrative only and should not be taken in any way as a restriction on the generality of the invention described above.

EXAMPLE 1

Mycoplasma hyopneumoniae media

Friss Media

Hovind-Hougen, K., Friss, N.F., Research in Veterinary Science, 1991, 51, pp
5 155-163, "Morphological & Ultrastructural Studies of M. flocculare and M. hyopneumoniae in vitro".

250 ml Hanks BSS
140 ml Water
10 1.5 gm Brain Heart infusion
1.6 gm PPLO Broth w/o CV
Autoclave at 120°C for 20 minutes
18 ml Yeast Extract (100g YSC-2 Sigma in 750 ml)
3.7 ml 0.2% DNA in 0.1% Na₂CL₃
15 5.14 ml 1% -NAD
0.6 ml 1% Phenol red

Adjust to pH 7.3 to 7.4

Filter through 0.45 um, 0.2 um membrane, store at 4°C.

20 Add sterile Horse or Pig serum to 20%
and Antibiotics prior to use

Etheridge Media

Etheridge, J.R., Cottew, G.S., Lloyd, L.C., Australian Veterinary Journal, 1979,
25 August 55, pp 356-359, "Isolation of Mycoplasma hyopneumoniae from lesions in
experimentally infected pigs".

	<u>Materials</u>	<u>For 600 mls</u>
	Hanks BSS	18.9 ml
30	Hartleys Digest broth	1.28 gm
	Heart Infusion broth	1.65 gm
	Lactalbumin hydrolysate	2.21 gm

Glucose	4.41 gm
Yeast Extract autolysate	8.82 ml
Pig Serum (filtered)	163 ml
1% NAD	6.17 ml
1% Phenol red	1.32 ml
0.2% DNA in 0.1% Na ₂ CO ₃	4.41 ml

Make up to 600 ml with MQ water (about 350 - 400 ml)

Adjust pH to 7.4 and filter through: 3.0 um, 0.8 um, 0.45 um, 0.2 um.

10 Store at 4°C.

Development of Immune Sows

Cull sows and naive gilt (unmated sow designated Dookie).

15 Challenged on numerous occasions, with culture grown M. hyopneumoniae and lung homogenate. Given intranasally and intratracheally. Period of challenge - from September, 1991 to 21st January, 1992.

Tiamulin antibiotic given 31st January, 1992 to 4th February, 1992. Rested for approximately 8 weeks.

Infectious Challenge

20 120 ml of frozen culture of M. hyopneumoniae strain Beaufort, spun down (12,000 xg, 20 min.) and resuspended in 50 ml complete medium and cultured overnight at 37°C. The overnight culture was centrifuged (12,000 xg, 20 min.) and the mycoplasma cells resuspended in 10 ml serum free mycoplasma culture medium. The 10 ml of concentrated mycoplasma was administered to anaesthetised immune sows
25 via a catheter to ensure the inoculum was placed into the trachea.

Three of four days post-challenge, the sows were killed, and lymph nodes draining the lungs taken - these included the left and right tracheobronchial lymph nodes, and the lymph nodes located at the bifurcation of the trachea.

30 Antibody probes were prepared from pig lymph nodes and utilised to detect putative protection antigens as described in Australian Patent Application 49035/90 referred to above. Separate cell cultures were obtained from individual lymph nodes. Culture supernatants were harvested after 5 days of culture.

Antigen Preparation

Mycoplasma hyopneumoniae strain Beaufort was cultured in Etheridge media until the pH had dropped to between 6.8 and 7.0. Cells of M. hyopneumoniae were harvested from culture by centrifugation at 12,000 xg for 20 min., washed 4 times with either sterile PBS or 0.25 M NaCl and then the pelleted cells extracted with one of the following.

(i) Sodium dodecyl sulphate (SDS)

The cell pellet was resuspended in 0.2% SDS and extracted for 2 hours at 37°C. Insoluble material was pelleted from the extract at 12,000 xg for 10 min. and the soluble extract run on SDS-polyacrylamide gel electrophoresis (SDS-PAGE).

(ii) Triton X-114

The method of Bordier (J. Bio. Chem. 1981, 256:1604-1606) was used to selectively extract membrane proteins using the non-ionic detergent Triton X-114.

The cell pellet was resuspended in cold PBS to 2 mg/ml protein and a cold pre-condensed solution of TX-114 added to give a final concentration of 1% (v/v) TX-114. Extraction was achieved by incubation overnight at 4°C with gentle mixing. Insoluble material was removed by centrifugation at 12,000 xg for 20 min. at 4°C. The Triton X-114 soluble membrane proteins were then obtained by achieving a phase separation at 37°C.

Proteins soluble in TX-114 phase were precipitated with 80% ethanol in the presence of carrier dextran (80,000 molecular weight) at -70°C overnight. The proteins were collected by centrifugation at 12,000 xg for 30 min. and dissolved to 500 ug/ml in 4 M urea.

Identification of Antigens

Six antigens were identified utilising the above-mentioned technique. The identified antigens were those that were consistently identified by the antibody probes from the immune cultures and the Dookie gilt. The results are summarised in Table 1.

TABLE 1

	<u>Molecular Weight (kD)</u>	<u>Characteristics</u>

20 The resulting PCR products were visualised on a 1.5% agarose gel, excised, and
purified using Prep-a-Gene (BioRad). They were cloned by standard techniques into a
dideoxy tailed T-vector (Holton and Graham, Nucleic Acids Research 19: 1156, 1991)
and the nucleic acid sequence determined. The PCR product, obtained from the
reaction using primers F1 and F2 shown above, was of approximately 810 base pairs
25 and was shown by sequencing to code for the previously determined amino acid
sequence of the purified native 46-48kDa protein.

Nucleic Acid Sequence of 810 bp PCR Fragment 46-48kDa Antigen

The sequence "pMH48.1-4 sequence 1" shown below starts encoding from the
30 11th amino acid, threonine, of the mature protein. Sequence "pMH48.1-4 sequence 2"
is contained within the PCR fragment, and "pMH48.1-4 sequence 3" is located at the 3'
end of the PCR fragment, but within the open reading frame encoding the 46-48kDa

antigen.

Adjuvant Selection

10 Young piglets, 5-7 weeks of age, were immunised with identified antigen(s). The antigens include Triton X-114 extract and identified proteins of 46-48, 52-53, 60-64, 70-75, 90-94 and 110-114 kD, either singly or in combination. An immunising dose of antigen, containing between 5-100 µg protein, was given by intramuscular injection in combination with an adjuvant. An adjuvant is selected from

- 15 (i) Seppic Montanide ISA-50
- (ii) Quill A and other derivatives of saponin,
- (iii) oil in water emulsion employing a mineral oil such as Bayol F/Arlacel A,
- (iv) oil in water emulsion employing a vegetable oil such as corn oil, safflower oil or other with lecithin as emulsifier,
- 20 (v) aluminium hydroxide gel, and
- (vi) nonionic block polymer such as Pluronic F-127 produced by BASF (U.S.A.).

Immunising doses were given at 2-4 week intervals, the number of doses being

dependent on the adjuvant and amount of antigen, but preferably 2 to 3 doses are given.

Adjuvants were treated on the basis of being able to induce antibody titres, as measured by ELISA, and by assessment of induced cell-mediated immunity as tested
5 by Delayed-Type Hypersensitivity (DTH) reaction.

The results clearly show that mineral-oil type adjuvants are consistently superior at inducing antibody titres and DTH responses (Table 2). In particular an adjuvant marketed under trade designation Montanide ISA-50 and available from Seppic, Paris, France has been found to be suitable.

TABLE 2				
GROUP	Animal Number	DTH 24 Hour Response	DTH 48 Hour Response	Antibody Levels (450 nm)
CONTROL (Unvaccinated)	19	0	0	0.061
	11	0	0	0.010
	1	-	-	0.005
	15	0	0	0.038
	7	0	0	0.005

	5	+++	++	1.024
	23	+++	+	0.864
	16	+++	0	0.975
	21	+	±	0.954

5 TABLE 2: Antibody levels and DTH responses in pigs measured 2 weeks after the third injection of antigen from M. hyopneumoniae. (- = no response; ± = faint reddening; + = faint reddening and swelling; ++ = reddening; +++ = swelling with or without reddening).

Protection Pen Trial

Groups of 9 young piglets, 6 weeks of age, were immunised with purified and semi-purified antigens as shown in Table 3 below. The antigens were purified on reversed-phase HPLC using a formic acid solvent system with an acetonitrile gradient.

5 Antigens were resolubilised in 4 Molar urea before incorporation in mineral oil adjuvant.

The immunisation schedule is as shown in Table 2.

ALL PROTEIN ESTIMATIONS DONE BY "BCA" PROTEIN ASSAY (Pierce, Illinois, U.S.A.

20 Protection from infection with Mycoplasma hyopneumoniae was assessed by infectious

challenge 2 weeks after the final immunisation. Infectious challenge was achieved by intranasal administration of 10ml of a 10% (w/v) lung homogenate, prepared from infected lung, and by housing test piglets with previously infected piglets. Four weeks after infectious challenge, the animals were killed and the extent and degree of lung lesions assessed (Table 4).

TABLE 4
Pen Trial of Antigens of Mycoplasma Hyopneumoniae

Group No.	No. Pneumonia Free (%)	Median Lung Lesion Score	% Reduction (from Median)
Controls	1 (11)	13	0%
62 kD	0 (0)	5	61%
74+52 kD	3 (33)	6.75	48%
48 kD	2 (22)	6.25	52%
